Home Improvement House Predictions

Author: Deztany Jackson

Business Understanding

Real Estate agents in King County, Seattle are evaluating the neighborhoods to encourage current home owners of he benefits of improving and upgrading their property value. Housing data from King County was used to develop linear regressions models to support future price prediction.

As a new data scientist I want to build up my clientele. I am working with the real estate agents in the area to build my netowrk as they increase theirs.

The primary stakeholders are real estate agents because of their wide use cases, network, domain knowledge and their incentive for home owners to increase their property value. They can also use this for getting a jump start on marketing to potential home buyers. The same predictions could be useful for the homeowners, potential buyers and even those in the remodeling and construction business. Because of their connection and real estate agents are able to influence a larger community's property value which as greater impact than convinving individual homeowners. The area attracts new implants from tech jobs. A great number of these people (as singles or families) may be looking to buy or rent.

This model is used as an intial model supporting course predictions. The main attributes used to support model prediciton are: Condition and Grade.

The main attributes used to support model creation are:

- 'bedrooms', 'bathrooms', 'sqft_living', 'sqft_lot', 'floors',
- 'waterfront', 'yr_built', 'zipcode', 'cond_num', 'grade_num' I would not guarantee the price predictions are 100% accurate, but will be useful to support general predictions.

The model used accounts for 67% variability. This means there are things that the model still doesn account for in making predictions.

[Phase 1 Project Description \(<https://learning.flatironschool.com/courses/4964/pages/phase-2-project-description>\)](https://learning.flatironschool.com/courses/4964/pages/phase-2-project-description), 2022

Data Understanding

This project uses the King County House Sales dataset (from GitHub project repo). This can be found in several locations: [Git Hub Data \(<https://github.com/learn-co-curriculum/dsc-phase-2-project-v2-3/tree/main/data>\)](https://github.com/learn-co-curriculum/dsc-phase-2-project-v2-3/tree/main/data) & [Kaggle \(<https://www.kaggle.com/datasets/harlfoxem/housesalesprediction>\)](https://www.kaggle.com/datasets/harlfoxem/housesalesprediction).

The data is in the format of "csv". The initial data used in the modeling will start with 20 of possible attributes. As modeling progresses certain attributes (features) will be processed, transformed and possibly removed.

```
In [1]: 1 #Imports necessary intial libraries
2
3 import pandas as pd
4 import numpy as np
5 import seaborn as sns
6 import matplotlib.pyplot as plt
7 %matplotlib inline
8
9 #Allowing for tables to have longer scroll capability
10 pd.set_option('display.max_rows', 500)
```

The imported data is the entire initial dataset. This will be scoped down before the initial understanding to support the core modeling needs with the limited time available. Starting with the entire dataset could potentially support a more accurate model with the increase of the attributes to choose from. We will settle for good enough with the dataset we have.

In [2]:

```

1 #Import of data to explore, make the id the index column
2 #The full entire dataset.
3 df = pd.read_csv('data/kc_house_data.csv', index_col=0)
4 #displaying the intial top five
5 df.head()

```

Out[2]:

	date	price	bedrooms	bathrooms	sqft_living	sqft_lot	floors	waterfront	v

Using shape to check size of dataset, rows and columns. Column names and amount are a key to track of through data preparation.

```
In [6]: 1 #Check size of the data set
         2 kc_df.shape
```

Out[6]: (21597, 11)

The following features are all numerical and categorical. The describe function only gives out for numerical numbers, not categorical (objects). The features of "yr_built", "bathroom", "bedroom" and "zipcode" are numbers and used to classify and count values. The rest are numerical cardinal values. The names of the features are generally self explanatory and will stay the same.

The features (not pictured below) of "condition" and "grade" picture are categorical strings, but will potential change to numerical values for ease of use.

Ref: Numerical Numbers, Rod Pierce (<https://www.mathsisfun.com/numbers/cardinal-ordinal-nominal.html>).

Initial Features Used

- **King County Table**
 - Rows: 21597
 - Features: 11
 - "id" is not a feature used in the modeling

Cardinal Numbers

- **price - (Target Variable)**
 - Description: Price is the amount of the house in context of the current attributes.
 - Type: Float Number
 - Expectation/Comment: Price will be our target variable. We will want to see after developing a solid model the varying of attributes would effect price. The price difference after an "upgrading" the home is also needed.
- **bedrooms**

- Description: Number of bedrooms for the given home
- Type: Int Number
- Expectation/Comment: Will evaluate how well this impacts the model.
- **bathrooms**
 - Description: Number of bathrooms for the given home
 - Type: Int Number
 - Expectation/Comment: It has the second highest correlation value against price. These are .25, .5 and .75 are used in addition to whole numbers. .25-Sink; .5-Sink and Toilet; .75-Sink, Toilet and Shower,/Bath; 1 - Everything
- **sqft_living**
 - Description: The size of the livable space in the house
 - Type: Int Number
 - Expectation/Comment: We will assume larger will amount gather more money.
- **sqft_lot**
 - Description: The size of the lot
 - Type: Int Number
 - Expectation/Comment: We will assume larger will gather more money.
- **floors**
 - Description: The Number of Floors.
 - Type: float Number
 - Expectation/Comment: We are not using the other attributes that compliment the number of floors. Sometimes one floor could be desirable. It would be hard to understand the house is architected with floors. It could be one floor and a basement, or two floors and no basement.

Nominal Numbers

- **yr_built**
 - Description: Year when house was built
 - Type: Int Number
 - Expectation/Comment: It could give context to the grade and condition. This may be useful for changing variables for prediction purposes
- **zipcode**
 - Description: ZIP Code used by the United States Postal Service
 - Type: Int Number
 - Expectation/Comment: The Zipcode will be there to help add to the business case. It can be helpful in creating collection of houses to focus on.

Categorical Objects

- **waterfront**
 - Description: Whether the house is on a waterfront
 - Type: Object String
 - Expectation/Comment: There isn't any information on what type of water. For those that are Null, we will fill Null with Unknown
- **condition**
 - Description: How good the overall condition of the house is. Related to maintenance of house.
 - Type: Intial Object String (Transformed to Int) - 5 Values

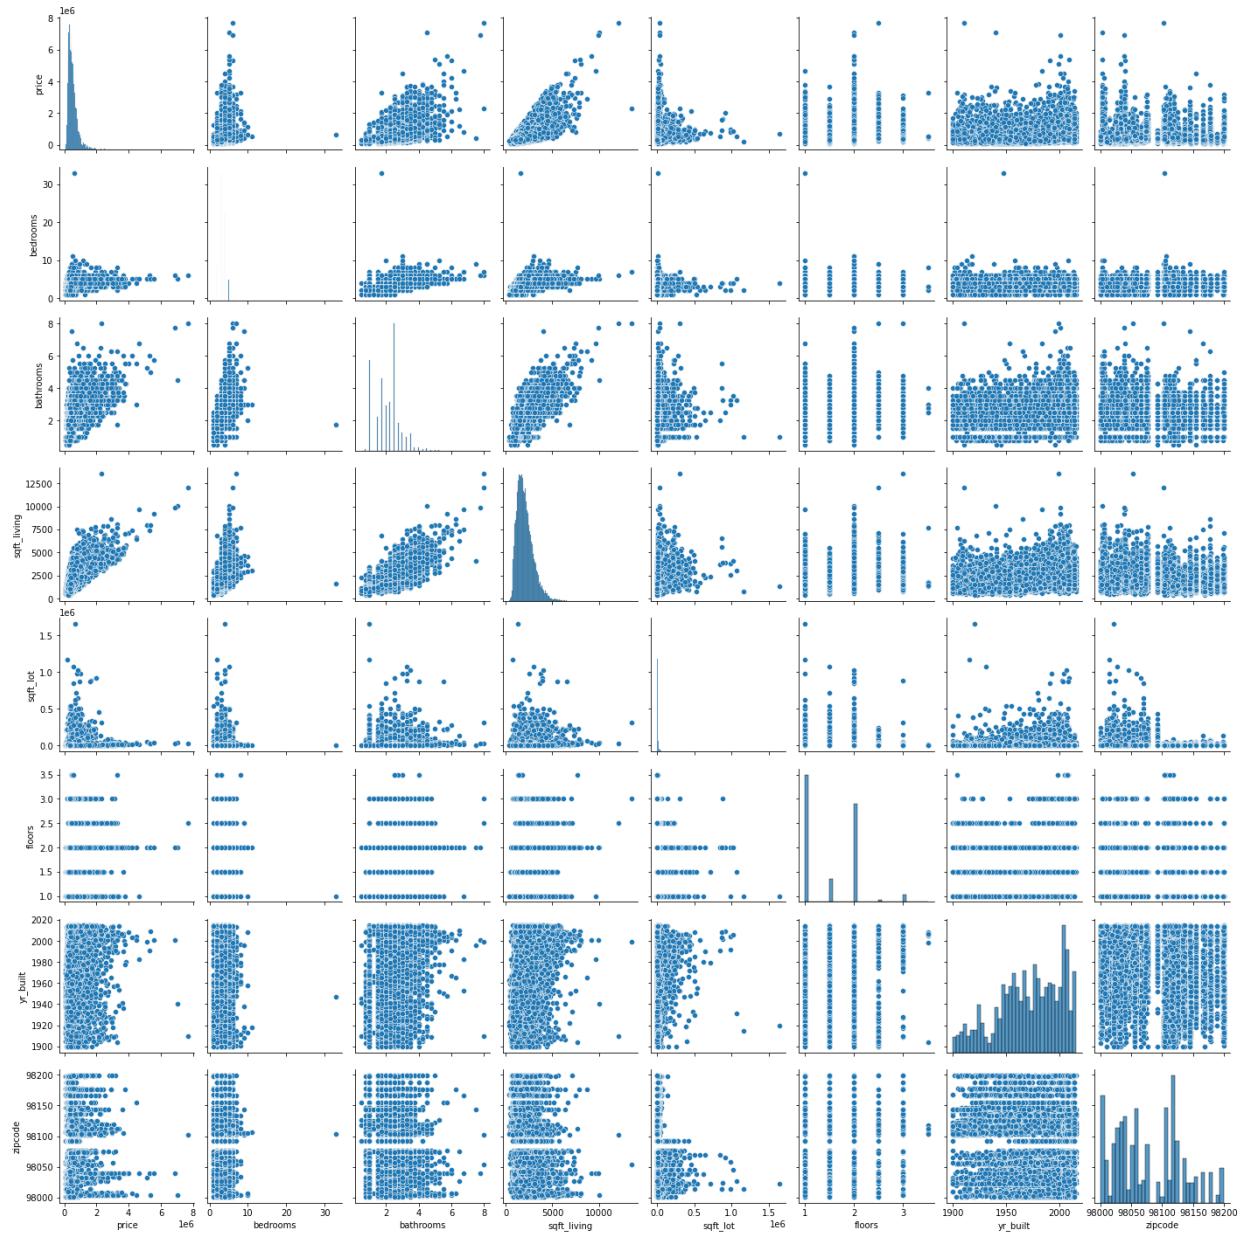

- Expectation/Comment: This paired with the grade may be the top useful in changing for prediction. Will be transformed into number from string later in model.
- **grade**
 - Description: Overall grade of the house. Related to the construction and design of the house.
 - Type: Initial Object String (Transformed to Float) - 13 Values
 - Expectation/Comment: This paired with the condition may be the top useful in changing for prediction. Will be transformed into number from string later in model.

Viewing and counting the values of the categorical features. We can assess what the best route to work with these is. Do we change to ordinal numbers or process this in the future using techniques like One Hot Encoding? For the "condition" and "grade" mapping numbers to the values will be used.

A broad view of the distribution of the features help understand the possible transformation needs of the data. Looking to see if the data is linear and/or normal distributed. The sqft_living looks the most linear against price. Most of the data is skewed and not normally distributed. Log-transformation and normalization should help the continuous data during the modeling.

```
In [8]: 1 #Pair plot for quick view of the datasets distribution and linearity
2 sns.pairplot(kc_df)
3
```

Out[8]: <seaborn.axisgrid.PairGrid at 0x7f8b06714d00>

Data Preparation

Data preparation happens throughout the modeling process in iteration as new information is known. There will be some preparation (e.g. data transformation and scaling) that will happen as we split the training and test data from one another. This is to protect against data leakage.

Looking further into the categorical data, to assess future processing needs.

```
In [9]: 1 #Viewing the values and their count for a feature
         2 kc_df[["condition"]].value_counts()
```

```
Out[9]: condition
          Average      14020
          Good        5677
          Very Good    1701
          Fair         170
          Poor         29
          dtype: int64
```

Using the "Column Names" file description and [King County Glossary, Building Conditions \(<https://info.kingcounty.gov/assessor/esales/Glossary.aspx?type=r>\)](https://info.kingcounty.gov/assessor/esales/Glossary.aspx?type=r) the string and values mapping was found and used. Even though OHE can be performed on the string values in the future. Having numbers makes it easier for data processing and manipulation (on new data or modified test data) for predictions.

```
In [10]: 1 #Creating a dictionary to map to the string values for condition
          2 cond_num = {'Very Good':5, "Good": 4, 'Average': 3, "Fair": 2, "Poor": 1
          3 }
```

```
In [11]: 1 #Applying the dictionary to map to the values of the original values

3            3 Poor          1
dtype: int64
```

Dropping the original columns of condition and grade. This is essentially duplicate information as the cond_num and grade_num.

```
In [18]: 1 #drop the original condition and grade columns
          2 kc_df = kc_df.drop(["condition", "grade"], axis = 1)
          3 kc_df.head()
```

Out[18]:

	price	bedrooms	bathrooms	sqft_living	sqft_lot	floors	waterfront	yr_built	zipcode
id									
7129300520	221900.0	3	1.00	1180	5650	1.0	NaN	1955	981
6414100192	538000.0	3	2.25	2570	7242	2.0	NO	1951	981
5631500400	180000.0	2	1.00	770	10000	1.0	NO	1933	980
2487200875	604000.0	4	3.00	1960	5000	1.0	NO	1965	981
1954400510	510000.0	3	2.00	1680	8080	1.0	NO	1987	980

The "waterfront" feature is the only feature that has "NaN". These values will be imputed with a value of "Unknown" than deleted or imputed with "No". The Null values make up over ~10% of the data set. This could impact training of the model adversely because the limited data. Less than 1% of the known homes have a waterfront view "No" may seem like a conservative choice to input, but using "Unknown" allows future data exploration if more information becomes available.

```
In [19]: 1 #Checking for waterfront Null counts
          2 kc_df[["waterfront"]].isna().value_counts()
```

```
Out[19]: waterfront
          False      19221
          True       2376
          dtype: int64
```

```
In [20]: 1 #Checking waterfront current value counts
          2 kc_df[["waterfront"]].value_counts()
```

```
Out[20]: waterfront
          NO      19075
          YES     146
          dtype: int64
```

If waterfront becomes a main feature it is good to understand which home types the Null is associated with. It seems the "average" and "good" grade home are traced to much of the Null values. If they have space for home repair, having a more accurate value of "waterfront" could turn out helpful for real estate agents to market.

```
In [21]: 1 #Checking to see which house types these Null values affect
          2 kc_df[kc_df["waterfront"].isna()]["grade_num"].value_counts()
```

```
Out[21]: 7      1000
          8      656
          9      295
          6      228
          10     116
          11     42
          5      30
          12     7
          4      2
          Name: grade_num, dtype: int64
```

Usually it is better to fill in "NaN" after train and test split to prevent data leakage. Because filling in unknown as no effect on the other features, decided to do it before.

```
In [22]: 1 #Replaces "NaN" with "Unk"
          2 kc_df["waterfront"].fillna("Unk", inplace = True)
          3
          4 #Check NaN Count after replacing "NaN"with "Unk"
          5 print("Values: ",kc_df[["waterfront"]].value_counts())
          6
          7 print("Waterfront Null Values: ", kc_df[["waterfront"]].isna().sum())
```

```
Values:  waterfront
          NO      19075
          Unk     2376
          YES     146
          dtype: int64
          Waterfront Null Values: 0
          dtype: int64
```

Remove duplicate values from the dataset. This could be from clerical issues multiple data entries.

```
In [23]: 1 #Remove the duplicate rows from data set
2 kc_df = kc_df.drop_duplicates()
3 print (kc_df.duplicated().sum(),kc_df.value_counts().sum())
```

0 21590

Training and Testing & Cross Validation Approach

Predicting new home prices comes after training and testing the model. We will split our data set into 80% training set and 20% testing. The train/test split is used for intial model validation. Kfold cross validation will also be used. This allows the dataset to be split into "train" and "test" and then when the training data is used with cross validation it will be split into "training" and "validation" data.

The target value is the "price" value. This will be set to "y" and the rest of the data will be in "X". This is then used to do the initial train/test split.

We do not want the test data to be trained with the training data. This is data leakage and can distort the training process.

```
In [24]: 1 # Importing library to split the data into training and test data for ml

Reviewing the statistics on the y_train and y_test value for current understanding and future comparison

Baseline Modeling (1)

Initial Correlation

The initial linear regression model will be done with the highest correlated feature. This will be considered our baseline model. From here we will do several iterations to see if we can improve the model's performance with different techniques.

Check for the highest correlated values to the target variable "price". Correlation works on numerical values, not categorical ones.

In [29]:

```

1 #Print out correlation values in dataframe
2 #This is done with the "price" value in the dataset.
3 corr = kc_df.corr()
4 corr

```

Out[29]:

	price	bedrooms	bathrooms	sqft_living	sqft_lot	floors	yr_built	zipcode
price	1.000000	0.308835	0.525933	0.701938	0.089868	0.256948	0.054015	-0.053381
bedrooms	0.308835	1.000000	0.514567	0.578211	0.032448	0.178196	0.155831	-0.154143

zipcode	-0.053381	-0.154143	-0.204782	-0.199751	-0.129583	-0.059711	-0.347430	1.000000
cond_num	0.036039	0.026450	-0.126446	-0.059526	-0.008894	-0.263915	-0.361447	0.002910
grade_num	0.668077	0.356788	0.665881	0.763031	0.114826	0.458705	0.447723	-0.185850

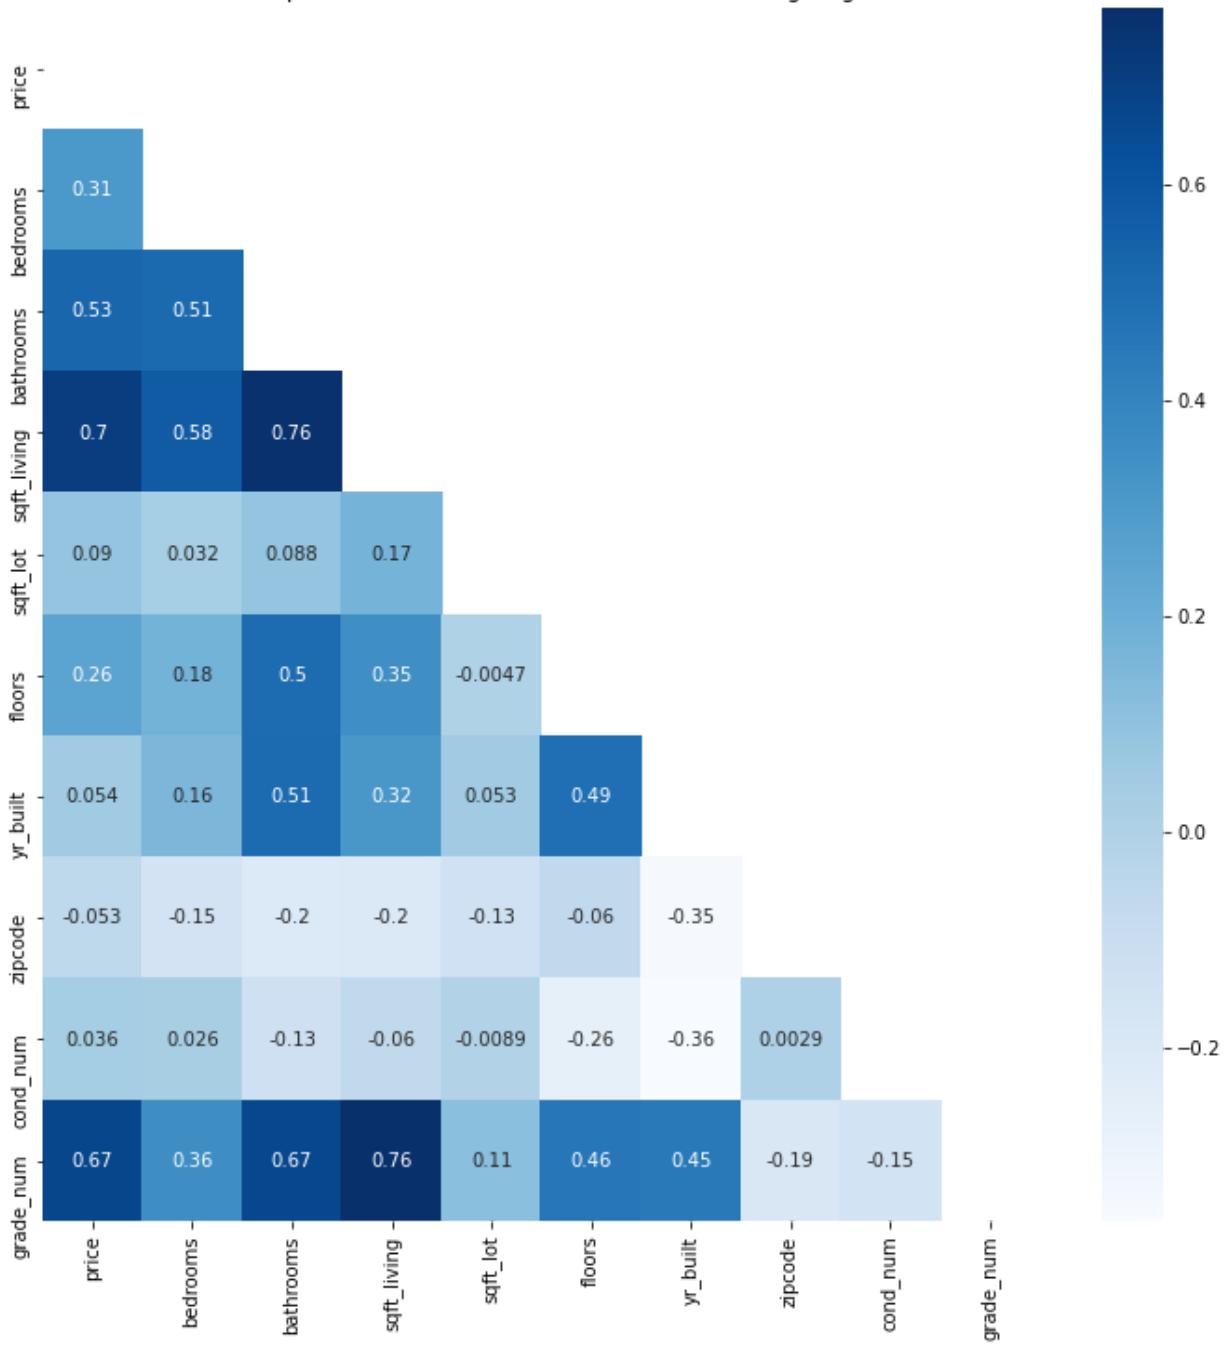

The most correlated is the sqft_living with (.7), the least is the zipcode with (-.05). Below this correlation table will be visualized in a heatmap.

Heatmap: [Ref: Phase 2, #20 Linear Reg Lab \(https://github.com/learn-co-curriculum/dsc-linear-regression-lab/tree/solution\)](https://github.com/learn-co-curriculum/dsc-linear-regression-lab/tree/solution)

In [30]:

```
1 # Set up figure and axes
2 fig, ax = plt.subplots(figsize=(12,12))
3
4 # Plot a heatmap of the correlation matrix, with both
5 # numbers and colors indicating the correlations
6 sns.heatmap(
7     # Specifies the data to be plotted
8     data=corr,
9     # The mask means we only show half the values,
10    # instead of showing duplicates. It's optional.
11    mask=np.triu(np.ones_like(corr, dtype=bool)),
12    # Specifies that we should use the existing axes
13    ax=ax,
14    #Color of the heatmap
15    cmap="Blues",
16    # Specifies that we want labels, not just colors
17    annot=True,
18
19 )
20
21 # Customize the plot appearance
22 ax.set_title("Heatmap of Correlation Between Attributes (Including Targ")
23
24 plt.savefig("images/Int_Corr_2.png", dpi=99)
```

Heatmap of Correlation Between Attributes (Including Target)

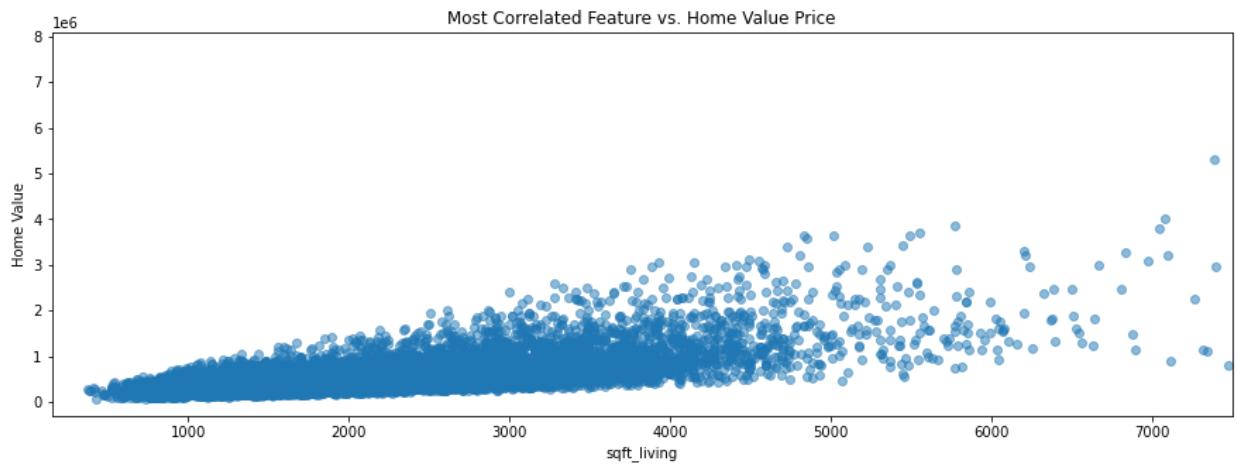

The "sqft_living" feature has the highest correlation of .7 with the "price". The "grad_num" feature is the second highest correlated with the "price". This is good to know because this will be one of the attributes changed during predictions. The "zipcode" feature has a negative correlation value. "Bathrooms" and "sqft_living" are highly correlated as well. These correlations are the only ones above .7. This dataset doesn't have a really high correlation with the "price" feature or with each other.

Below we will plot the most correlated feature against price. This will let us see if this distribution is linear for our baseline model.

```
In [31]: 1 #Strongest numerical feature from the heatmap
          2 most_correlated_feature = "sqft_living"
```

```
In [32]: 1 #Plot a scatter plot "Most Correlated Feature vs. Home Value"
          2 fig, ax = plt.subplots(figsize = (15,5))
          3
          4 ax.scatter(X_train[most_correlated_feature], y_train, alpha=0.5)
          5 ax.set_xlabel(most_correlated_feature)
          6 ax.set_ylabel("Home Value")
          7 ax.set_title("Most Correlated Feature vs. Home Value Price");
          8 plt.xlim([150, 7500])
          9 plt.savefig("images/Linear_Price_3.png", dpi=99)
```

The graph shows a fairly linear data plot. The larger the sqft gets with the increase of price the more outliers arise.

Baseline Model - Basic Train/Test Split

Modeling the baseline feature using the basic train/test split first then a kfold validation method.

Modeling using linear regression approach. This looks at the relationship between dependent (y) and independent (x) values.

- The "fit" method learns something about the data.
- The "transform" method uses what it learned to transform the data.

The train and test data are separated but, the same process needs to be applied on each.

- During processing, fitting the data is done on the training data to learn. It is applied on the testing data using transform.

In [33]:

```

1 #Reshaping from a 1D series to a multidimensional array that the transfe
2
3 #Reshape training data to support modeling without error
4 X_train[most_correlated_feature]
5 X_array = np.array(X_train[most_correlated_feature])
6 newarr = X_array.reshape(-1,1)
7
8 #Reshape the test data to support modeling without error for single arr
9 X_test[most_correlated_feature]
10 X_array_test = np.array(X_test[most_correlated_feature])
11 newarr_test = X_array_test.reshape(-1,1)

```

In [34]:

```

1 #Showing the data prior and post reshaping
2 print(X_train[most_correlated_feature].shape,newarr.shape)

```

(17272,) (17272, 1)

In [35]:

```

1 #Importing Linear Regression library
2 from sklearn.linear_model import LinearRegression
3
4 #Initializing model
5 linreg = LinearRegression()
6 #Fitting training data
7 linreg.fit(newarr, y_train)
8 linreg.fit(newarr_test, y_test)
9 LinearRegression()

```

Out[35]: LinearRegression()

After we train the model. The train and test data is applied (.predict) to the trained linear regression model to predict the estimated y value ("price"). From here a R2 score and RMSE are calculated. The R2 allows us to see how well the test and train model are compared to each other and how much of the variation the model covers. The higher the R2 score the better. We would like the test R2 score to be higher than the trained model.

RMSE is used to measure distance between predicted and actual values. It measures how well the model predicts. The lower value the better (closer to zero is best). Usually the training data is higher than the test data, a lower test value supports the accuracy of the model.

- [RMSE Kaggle, 2020 \(<https://www.kaggle.com/general/215997>\)](https://www.kaggle.com/general/215997)
- [David Dalpiaz, 2020 \(<https://daviddalpiaz.github.io/r4sl/regression-for-statistical-learning.html>\)](https://daviddalpiaz.github.io/r4sl/regression-for-statistical-learning.html)

In [36]:

```

1 #Importing library to look at errors
2 from sklearn.metrics import mean_squared_error
3
4 #Y price Predictions for training and testing features
5 y_hat_train = linreg.predict(newarr)
6 y_hat_test = linreg.predict(newarr_test)
7
8 #Root Mean Square Error (np.sqrt of the MSE)
9 train_rmse = np.sqrt(mean_squared_error(y_train, y_hat_train))
10 test_rmse = np.sqrt(mean_squared_error(y_test, y_hat_test))
11
12 #r2 Score
13 Model_train_score = linreg.score(newarr,y_train)
14 Model_score = linreg.score(newarr_test,y_test)
15
16 print("Baseline Train/Test:")
17 print('Train RMSE ', train_rmse)
18 print('Test RMSE: ', test_rmse)
19 print()
20 print('Train Model Score: ', Model_train_score)
21 print('Test Model Score: ', Model_score)
22

```

Baseline Train/Test:

Train RMSE 260172.0361161922
 Test RMSE: 268864.35998011974

Train Model Score: 0.49091149233831743
 Test Model Score: 0.494749423259338

The test RMSE is currently high and worse than the training Error. They both are far from 0. The model will not generalize well for future test data. The reason is unclear, it may be irreducible noise. Will look into applying log transforming to certain continuous attributes in the dataset to see. The base model R2 scores are both round only .49, the test R2 is higher than the trained data. This base model isn't strong enough to support predicting prices. This tells us how well the model is at predicting the variance in dataset. There may be better features or a combination of a few that hopefully will increase the score.

Baseline Model- Kfold Validation

The original dataset is split into "train" and "test". We are applying the kfold validation to our training set which splits the training dataset into "train" and "validation". The amount of splits is set in the cv. The Kfold score will be a mean of the various splits.

In [37]:

```

1 #Importing cross validate and shuffle split.
2 #Shuffle split creates different values for splits and test size
3 from sklearn.model_selection import cross_validate, ShuffleSplit
4
5 #Splitting the dataset twith a .3 test size
6 splitter = ShuffleSplit(n_splits=3, test_size=0.3, random_state=42)
7
8 #Initialze as used estimator
9 baseline_model = LinearRegression(normalize= True)
10
11 #Baseline scores using kfold cross validation
12 #Most correlated feature - sqft_living
13 baseline_scores = cross_validate(
14     estimator=baseline_model,
15     X=X_train[[most_correlated_feature]],
16     y=y_train,
17     return_train_score=True,
18     cv=splitter
19 )
20
21
22 #Mean of the train and validation scores
23 print("Baseline Models:")
24 print("Current Kfold Train mean score:      ", baseline_scores["train_sc"])
25 print("Current Kfold Validation mean score: ", baseline_scores["test_sco"])
26 print()
27 #Training and validation Scores
28 print('Previous Train/Test Split Train Model Score: ',Model_train_scor
29 print('Previous Train/Test Split Validation Model Score: ', Model_score

```

Baseline Models:

Current Kfold Train mean score: 0.4884772214299433
 Current Kfold Validation mean score: 0.5000072841051805

Previous Train/Test Split Train Model Score: 0.49091149233831743
 Previous Train/Test Split Validation Model Score: 0.494749423259338

The Kfold method offers a higher validation mean score (.50) than the previous Train/Test score. Both offer a higher score than their associated training score. The kfold validation will be used in the future iterations of the model training.

Second Model with Categories and Numerical Features (2)

We will improve the baseline model by adding more features training more features(numerical and categorical). Additional features should support an increase a R2 score because it will help describe the dataset more. More processing of the data will occur across the training and testing data to support an improved model.

```
In [38]: 1 #Viewing the current columns in the dataset to use
          2 X_train.columns
```

```
Out[38]: Index(['bedrooms', 'bathrooms', 'sqft_living', 'sqft_lot', 'floors',
       'waterfront', 'yr_builtin', 'zipcode', 'cond_num', 'grade_num'],
      dtype='object')
```

```
In [39]: 1 #Specify the groups of features in list for specific plotting uses
          2 #sqft_living was plot above, therfore it is not in this numerical list
          3 #Not showing sqft living, cond_num and grade_num
          4 numerical = ['bedrooms','sqft_lot','floors',"bathrooms","yr_builtin", "z"]
          5 categoricals = ['waterfront']
```

Linear Reg Code Ref: [Phase 2, Topic 20 Linear Reg Lab \(https://github.com/learn-co-curriculum/dsc-linear-regression-lab/tree/solution\)](https://github.com/learn-co-curriculum/dsc-linear-regression-lab/tree/solution)

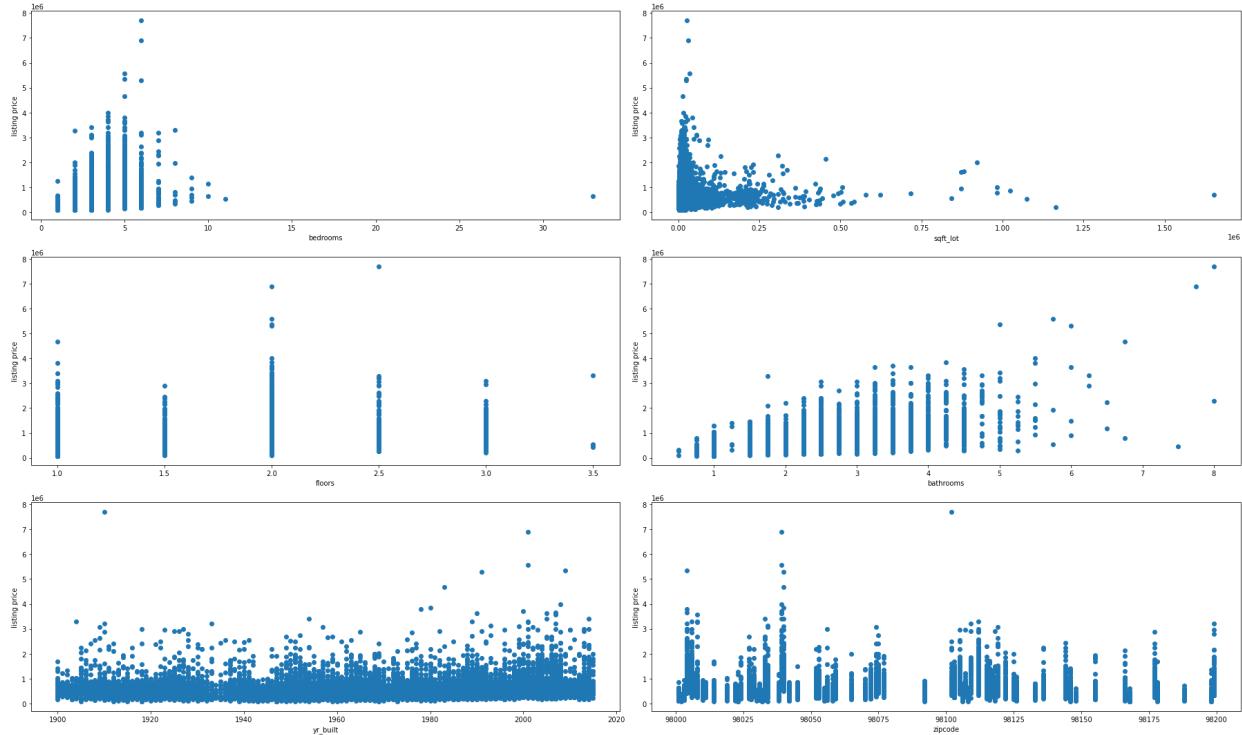

Plotting scatter plots to look which features would need further processing and transformaiton.

In [40]:

```

1 #Plotting scatter plots of numerical values except sqft_living
2 X_train_plot = X_train[numerical]
3
4 fig, axes = plt.subplots(ncols=2, nrows=3, figsize=(25, 15))
5 fig.set_tight_layout(True)
6
7 for ide, c in enumerate(X_train_plot.columns):
8     ax = axes[ide//2][ide%2]
9     ax.scatter(X_train_plot[c], y_train)
10    ax.set_xlabel(c)
11    ax.set_ylabel("listing price")
12
13 plt.savefig("images/Pairwise_4", dpi=99)

```

Checking for assumptions of model for all the numerical features .

From the continuous features sqft_living is the most linear, but skewed. The other skewed continuous features is the sqft_lot.

Log transformations will be performed on the sqft_living and sqft_lot because of their skewness. We will treat bathrooms,bedrooms, floors, zipcode , cond_num, grade_num, and yr_built as discrete variables and

"A heuristic you might use to select continuous variables might be a combination of features that are not object datatypes and have at least a certain amount of unique values." Ref: [Phase 2 Module 20, Feature Scaling and Norm \(<https://github.com/learn-co-curriculum/dsc-feature-scaling-and-normalization-lab/tree/solution>\)](#)

Data processing and transformation

Certain features from the dataset will be transformed. Log transformations will be performed on the sqft features and the "price" to normalize their data, due to their skewness. Because we already transformed the "condition" and "grade" features to numbers, we will apply the One Hot Encoding transformation to the "Waterfront" categorical feature.

The process of transforming the features. Ref Naming Categories after OHE: [Codementor](https://www.codementor.io/@abdelfettahbesbes/one-hot-encoding-in-data-science-1pe0lftu21) (<https://www.codementor.io/@abdelfettahbesbes/one-hot-encoding-in-data-science-1pe0lftu21>)

```
In [41]: 1 #Setting column names for one hot encoded variables
          2 categoricals
          3 cat_cols_encoded = []
          4 for col in categoricals:
          5     cat_cols_encoded += [f'{col[0:2]}_{cat}' for cat in list(X[col].uni
          6
```

```
In [42]: 1 cat_cols_encoded
```

```
Out[42]: ['wa_Unk', 'wa_NO', 'wa_YES']
```

Reminder, only some of the features will be transformed based on their type.

```
In [43]: 1 #Creating a list of the features to transform
          2
          3 #Features going through log-transformaiton
          4 log_feat = ["sqft_lot", "sqft_living"]
          5 #Features that will not be transformed
          6 discrete_col = ["bathrooms", "bedrooms", "yr_built", "zipcode", "floors", "c
          7 #OHE features
          8 categoricals = ['waterfront']
          9
```

```
In [44]: 1 #Reshape Y training data to support modeling without error for single a
          2
          3 Y_array_train = np.array(y_train)
          4 y_trainarr = Y_array_train.reshape(-1,1)
          5
          6 #Reshape the test data to support modeling without error for single arr
          7 Y_array_test = np.array(y_test)
          8 y_testarr = Y_array_test.reshape(-1,1)
```

The below code fits and transforms the data. The datasets are then fitting and transforming data. The X and y train and test datasets are being transformed. Because the X and y are different sets they have different transformers applied.

In [45]:

```

1 # import OneHotEncoder from sklearn.preprocessing
2 from sklearn.preprocessing import OneHotEncoder, FunctionTransformer
3
4 # Instantiate transformers
5 log_transformer = FunctionTransformer(np.log, validate=True)

          3 y_hat_test_sec = linreg_sec.predict(X_test_sec)
          4
          5 #Root Mean Square Error (if squared is set to False) It is low because
          6 train_rmse_sec = mean_squared_error(y_train_log, y_hat_train_sec, squared=False)
          7 test_rmse_sec = mean_squared_error(y_test_log, y_hat_test_sec, squared=False)
```

In [52]:

```

1 #Print out of errors and scores for current and previous models
2
3 print('Current Train RMSE (logged): ', train_rmse_sec)
4 print('Current Test RMSE(logged): ', test_rmse_sec)
5 print()
6 #Mean of the Current kfold validation scores
7 print("Current Model Kfold Train score:      ", second_scores["train_sco
8 print("Current Model Validation score:", second_scores["test_score"].me
9 print()
10 #Mean of the traing validation scores
11 print("Baseline Models:")
12 print("Previous Kfold Train mean score:      ", baseline_scores["train_s
13 print("Previous Kfold Validation mean score:", baseline_scores["test_sc
14 print()
15 #Train and validation Scores
16 print('Previous Train/Test Split Train Model Score: ', Model_train_scor
17 print('Previous Train/Test Split Validation Model Score: ', Model_score

```

Current Train RMSE (logged): 0.3148336380868248
 Current Test RMSE(logged): 0.30755351160737365

Current Model Kfold Train score: 0.6446907194384797
 Current Model Validation score: 0.6414405396108452

Baseline Models:
 Previous Kfold Train mean score: 0.4884772214299433
 Previous Kfold Validation mean score: 0.5000072841051805

Previous Train/Test Split Train Model Score: 0.49091149233831743
 Previous Train/Test Split Validation Model Score: 0.494749423259338

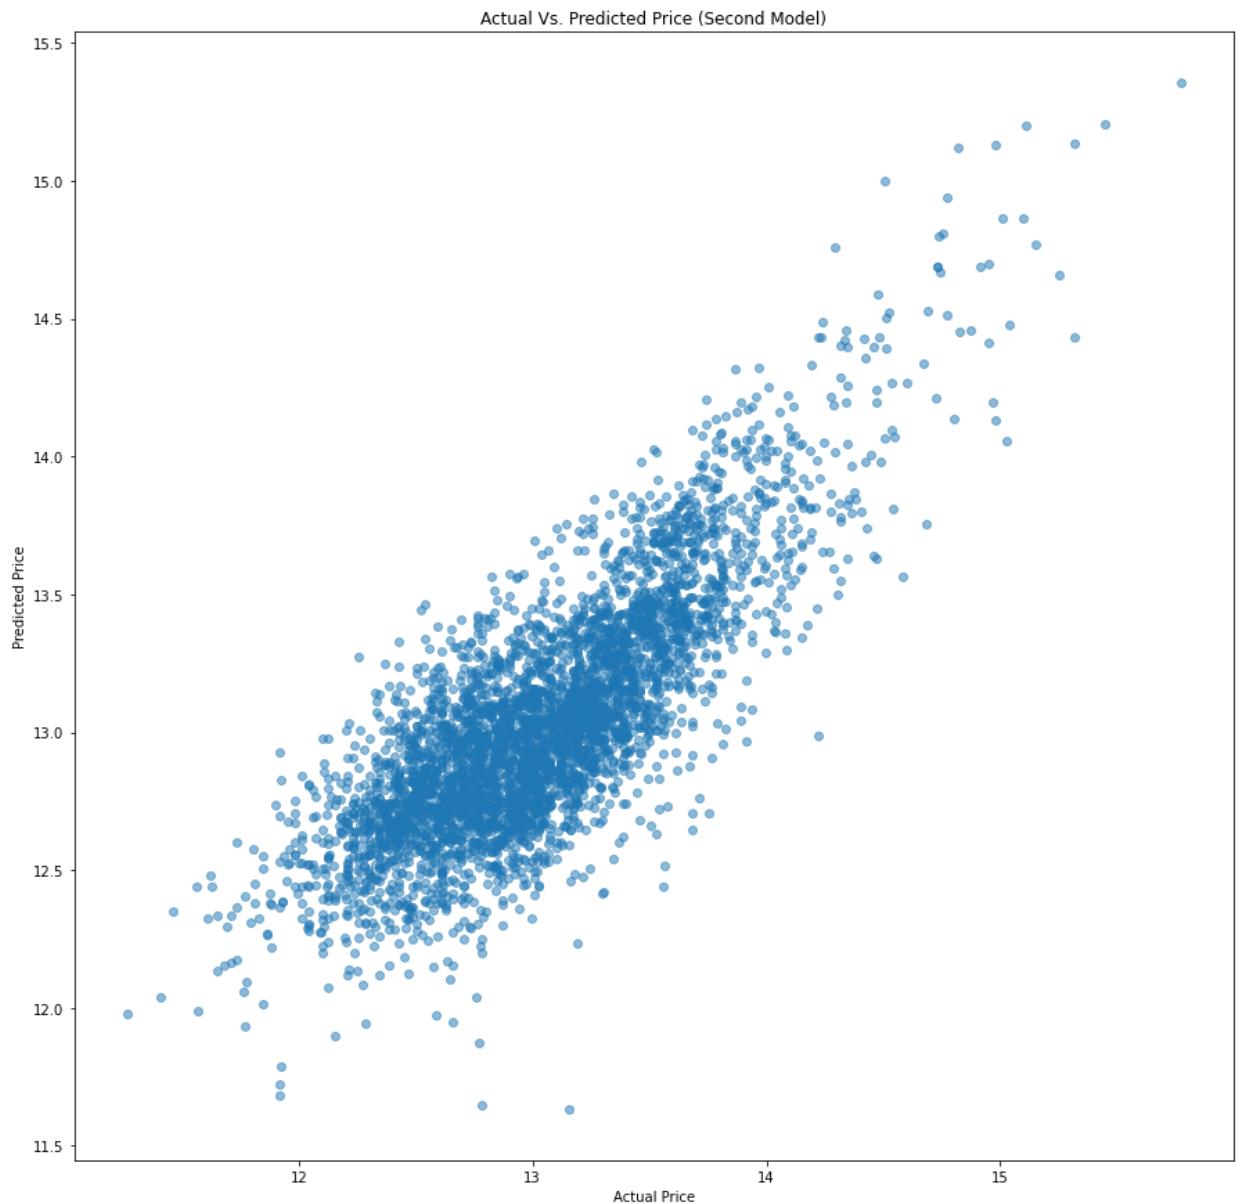

The current RMSE of the test data is less than that of the training data. This means the model is more generalized than before. The values are still higher than 0, but have decreased substantially with the transformations.

The current model has increase the R2 score for the validation model by ~(.14). This means we increased the ability for our model to understand the variance in the model by 14%. The validation model is not better than the train model score, there might be a slight overfitting if we use this.

So far we will keep this current model and improve.

In [53]:

```
1 #plotting the linearity zoomed in
2 fig, ax = plt.subplots(figsize = (15,15))
3
4 ax.scatter(y_test_log, y_hat_test_sec, alpha=0.5)
5 ax.set_title("Actual Vs. Predicted Price (Second Model)")
6 ax.set_xlabel("Actual Price")
7 ax.set_ylabel("Predicted Price")
8 #plt.xlim([0, 2500000])
9
10 plt.savefig("images/Act_Pred_5.png", dpi=99)
```

The predicted data is being plotted for a perfect fitted line. The graph shows linearity up until ~1 Million dollars, but a high number of outliers after this point.

Investigating Multicollinearity

Looking into further multicollinearity of the data. We want the features to be independent. The less they are, the more they can alter the model's fit.

```

Skew:	-0.014	Prob(JB):	1.82e-23			
Kurtosis:	3.380	Cond. No.	2.08e+08			

Notes:

[1] Standard Errors assume that the covariance matrix of the errors is correctly specified.

[2] The condition number is large, 2.08e+08. This might indicate that there are strong multicollinearity or other numerical problems.

Which ones features should be eliminated based on p value? We are assuming alpha level (significance level) of .05. If the p-value is above this, this let's us know we should reject these features. This is based on a hypothesis that these features are meaningful to the model.

Looks like there is a lot of multicolinearity in the model. The features that are above the needed p-value are:

- "wa_NO" .

Also, both "wa_NO" coefficient and the "zipcode" are outside of the confidence intervals, meaning they are outliers. The two most significant coefficients are the "grad_num" and "sqft_living" based on their std_err and high t value

Ref Statsmodel Interpretation [Tim McAleer, 2020 \(https://medium.com/swlh/interpreting-linear-regression-through-statsmodels-summary-4796d359035a\)](https://medium.com/swlh/interpreting-linear-regression-through-statsmodels-summary-4796d359035a)

We will run Recursive Feature Evaluation (RFE) to see if some of the same values are chosen to be removed.

Feature Recommendations with RFECV

Feature selection method that eliminates the weakest features depending on settings.

In [56]:

```

1 from sklearn.feature_selection import RFECV
2 #Features must be scaled to be used
3 from sklearn.preprocessing import StandardScaler
4 from sklearn.model_selection import cross_validate, ShuffleSplit
5
6 splitter = ShuffleSplit(n_splits=3, test_size=0.3, random_state=42)
7
8
9 X_train_for_RFECV = StandardScaler().fit_transform(X_train_sec)
10
11 #Initiate linear Regression model
12 model_for_RFECV = LinearRegression()
13
14
15 # Instantiate and fit the selector
16 selector = RFECV(model_for_RFECV, cv=splitter)
17 selector.fit(X_train_for_RFECV, y_train_log)
18
19
20 # Print the results Ref: [Phase 2, Topic 20, Linear Regression Lab]
21 print("Non Recommended Features")
22 #Creates a list for Recommended dropped columns
23 #The recommended dropped features will be False. If False, add to list
24 RFECV_rec_drop_col = []
25 for index, col in enumerate(X_train_sec.columns):
26     if selector.support_[index] == False:
27         print(f"{col}: {selector.support_[index]}")
28         RFECV_rec_drop_col.append(col)

```

Non Recommended Features

wa_NO: False

In [57]:

```

1 print("Rec P-value based drop: " "co_Poor", "wa_NO" )
2 print("Rec RFECV based drop: ", RFECV_rec_drop_col )

```

Rec P-value based drop: co_Poor wa_NO

Rec RFECV based drop: ['wa_NO']

The RFECV method agrees on dropping all the same features as the p-value test. On the next model all of the recommended features will be dropped.

In [58]:

```

1 #Checking current columns
2 X_train_sec.columns

```

Out[58]:

```

13 print()
14 #Mean of the traing validation scores
15 print("Baseline Models:")
16 print("Previous Kfold Train Mean Score:      ", baseline_scores["train_mean"])
17 print("Previous Kfold Validation Mean Score:", baseline_scores["test_mean"])
18 print()
19 #Train and validation Scores
20 print('Previous Train/Test Split Train Model Score: ', Model_train_score)
21 print('Previous Train/Test Split Validation Model Score: ', Model_score)

```

Current Train RMSE 0.3147718460539656

Current Test RMSE: 0.3075890371545622

Current Train Model Mean Score: 0.644673314060476

Current Validation Model Mean Score: 0.6414594822403191

Second Model Kfold Train Mean score: 0.6446907194384797

Second Model Validation Mean score: 0.6414405396108452

Baseline Models:

Previous Kfold Train Mean Score: 0.4884772214299433

Previous Kfold Validation Mean Score: 0.5000072841051805

Previous Train/Test Split Train Model Score: 0.49091149233831743

Previous Train/Test Split Validation Model Score: 0.494749423259338

In [68]:

```

1 print('Current Train Model Scorea: ', third_scores["train_score"])
2 print('Current Validation Model Scores: ', third_scores["test_score"])

```

Current Train Model Scorea: [0.64160177 0.64360325 0.64881492]

Current Validation Model Scores: [0.64847415 0.643949 0.6319553]

There isn't a big change in the third and second model R2 score even after feature selection. The test validation increased slightly as the train score decreased. They are very similar though. When looking at the specific fold splits, we can see there are runs where the validation score was larger than the training score.

Final model (4)

After modeling three iterations at similar score of ~.65 for the training and validation data, a final

model will be fit and used for predicton using the last dataset.

```
In [69]: 1 #Transform data set by changing the condition or grade and try to predi  
2 X_train_final = X_train_third  
3 X_test_final = X_test_third
```

```

```

```
In [75]: 1
2 #We will highlight three coeffieents that have been evaluated after log
3
4 print("Feature Coeffecient Impacts\n")
5 print(f"Grade Feature: For every one-unit increase in the Grade, the ho
6 print(f"Condition Feature: For every one-unit increase in the Condition
7 print(f"Sqft_living Feature: For every {inc_per}% increase in the sqft,
8
9
```

Feature Coeffecient Impacts

Grade Feature: For every one-unit increase in the Grade, the home value increases by about 26.0 %.

Condition Feature: For every one-unit increase in the Condition, the home value increases by about 3.0 %.

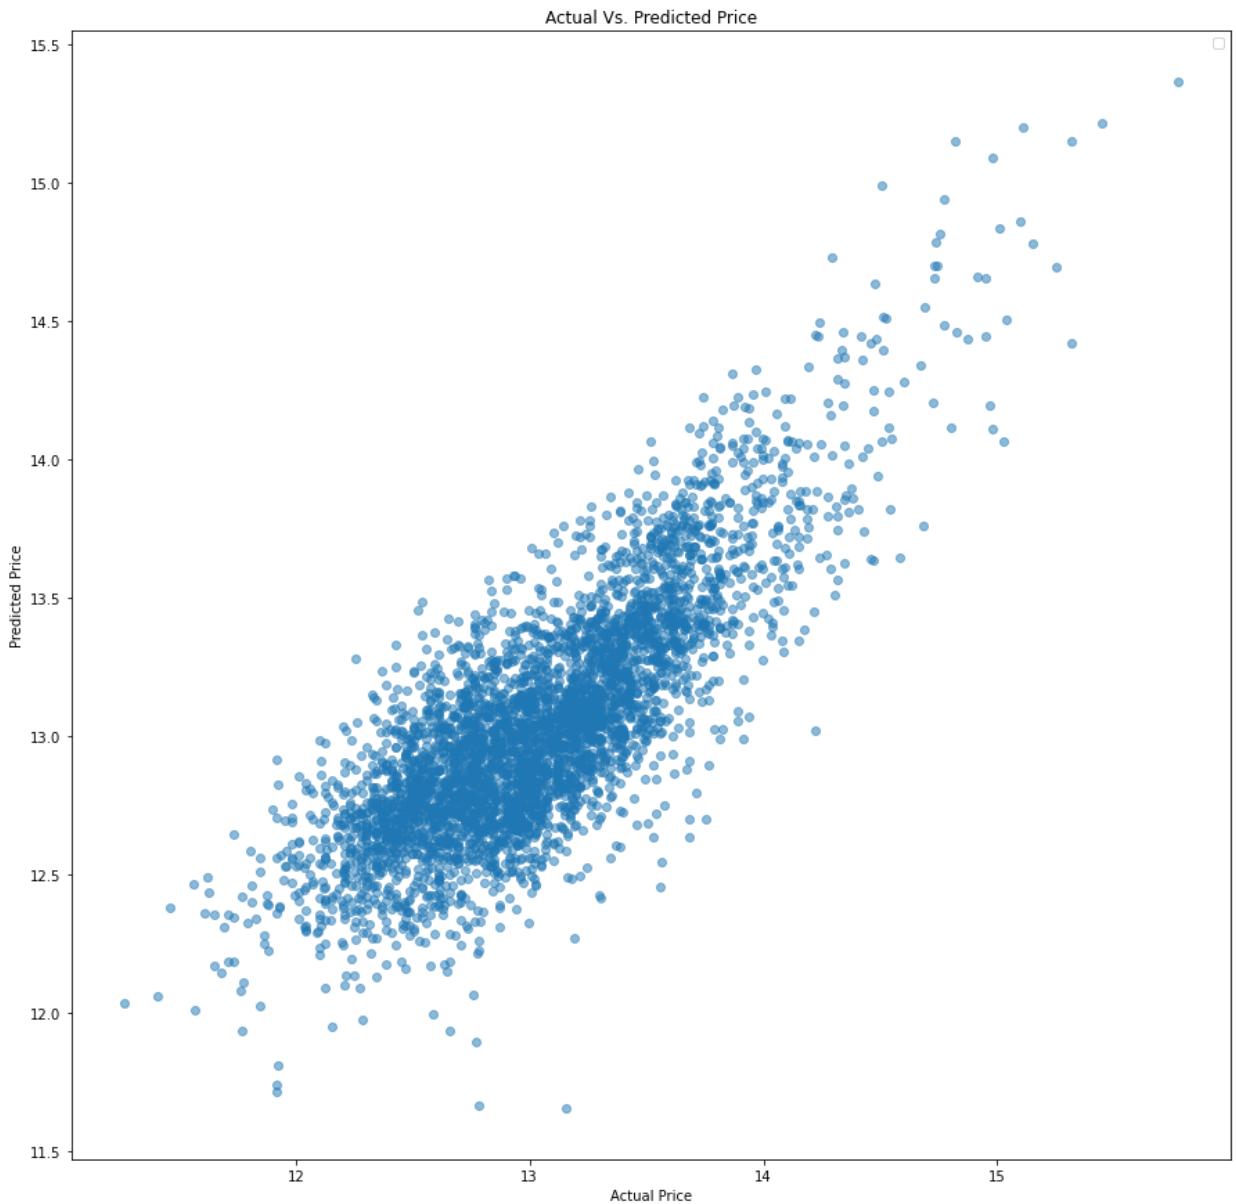

Sqft_living Feature: For every 5% increase in the sqft, the home value by about 20.0 %.

Linear Regression Assumption

In [76]:

```
1 fig, ax = plt.subplots(figsize = (15,15))
2
3 perfect_line = np.arange(y_test_log.min(), y_test_log.max())
4 ax.scatter(y_test_log, y_hat_test_fin, alpha=0.5)
5 ax.set_title("Actual Vs. Predicted Price")
6 ax.set_xlabel("Actual Price")
7 ax.set_ylabel("Predicted Price")
8
9 ax.legend();
10
11 plt.savefig("images/Lin_Assump6.png", dpi=99)
```

No handles with labels found to put in legend.

The perfect line is parallel to the scatter plot. The scatter plot has the same linear shape. It is still considered linear.

Normality Assumption

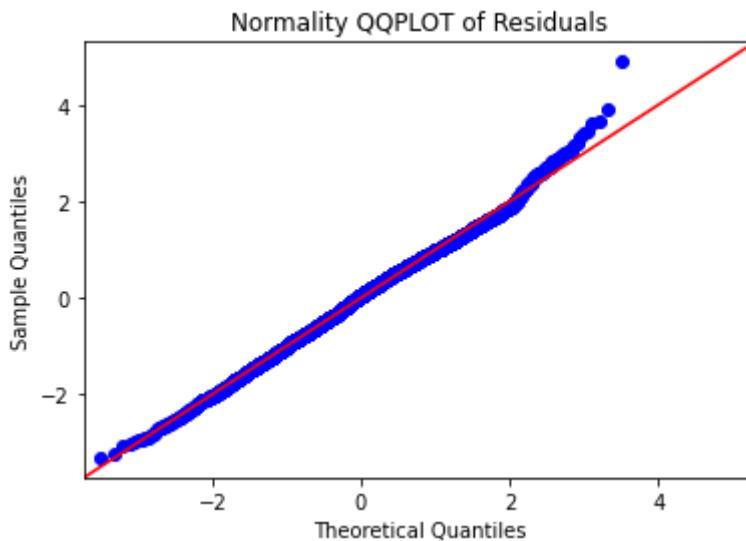

Model Regression [Ref: Phase 2, Model Reggression Lab Video \(\)](#)

In [77]:

```

1 import scipy.stats as stats
2 residuals = (y_test_log - y_hat_test_fin)
3 #QQPLOT
4 sm.graphics.qqplot(residuals, dist=stats.norm, line='45', fit=True);
5 plt.title("Normality QQPLOT of Residuals")
6
7 plt.savefig("images/Normality_7.png", dpi=99)

```

Using the QQ plot shows normality with a slight offshoot at the end.

Multicollinearity

In [78]:

```

1 from statsmodels.stats.outliers_influence import variance_inflation_factor
2 #Variance Inflation Factor
3 vif = [variance_inflation_factor(X_train_final.values, i) for i in range(X_train_final.shape[1])]
4 pd.Series(vif, index=X_train_final.columns, name="Variance Inflation Factor")

```

Out[78]:

bedrooms	24.645905
yr_built	7382.348064
zipcode	8235.823316
floors	15.333726
cond_num	33.895878
grade_num	116.375693
wa_YES	1.024235

Name: Variance Inflation Factor, dtype: float64

Wow! All the numerical values and two grade categorical values have high VIF except for "wa_Yes". There is a strong multicollinearity between these features. Dropping some of these features will support the multicollinearity problem. It is not clear what is the best combination of features is the

most effective for our problem. (In a different iteration, not pictured, some of these were dropped after these results; the multicollinearity dropped, but also the R2 score.)

Because we are using this model for prediction and not inference we can keep using the trained fitted model. If the goal is to understand specific individual features and how they impact the model, then multicollinearity is a major issue that needs to be solved.

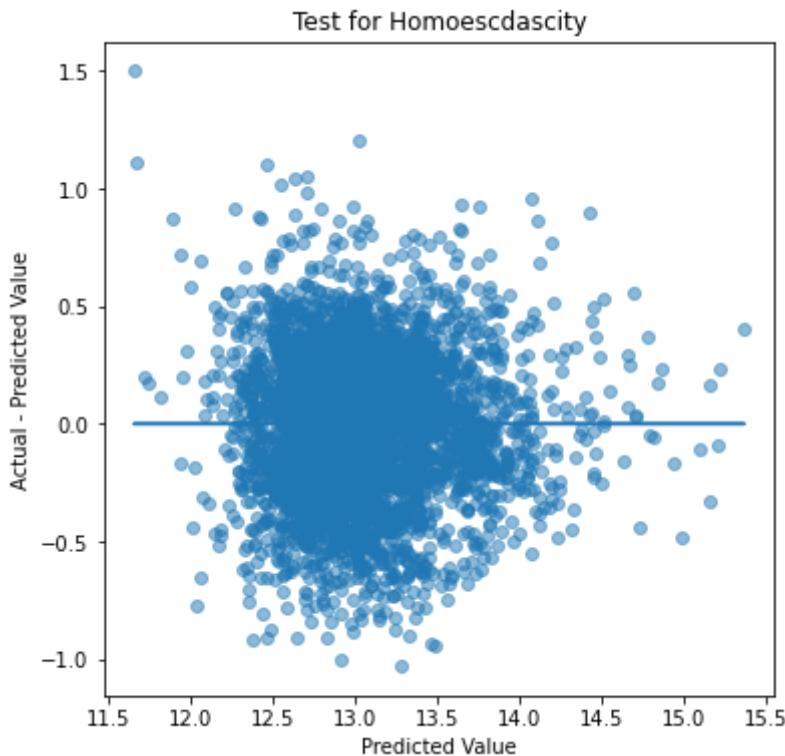

Homoescdasticity

In [79]:

```

1 fig, ax = plt.subplots(figsize = (6,6))
2 #Scatter plot of predictions and residuals
3 ax.scatter(y_hat_test_fin, residuals, alpha=0.5)
4 ax.plot(y_hat_test_fin, [0 for i in range(len(X_test_final))])
5 ax.set_xlabel("Predicted Value")
6 ax.set_ylabel("Actual - Predicted Value");
7 ax.set_title("Test for Homoescdascity")
8
9 plt.savefig("images/Homoesc_8.png", dpi=99)

```

Most of the residuals are homoescdastic. There are still plenty of outliers that can be drop or dealt with. Even with the outliers it generally passess the test.

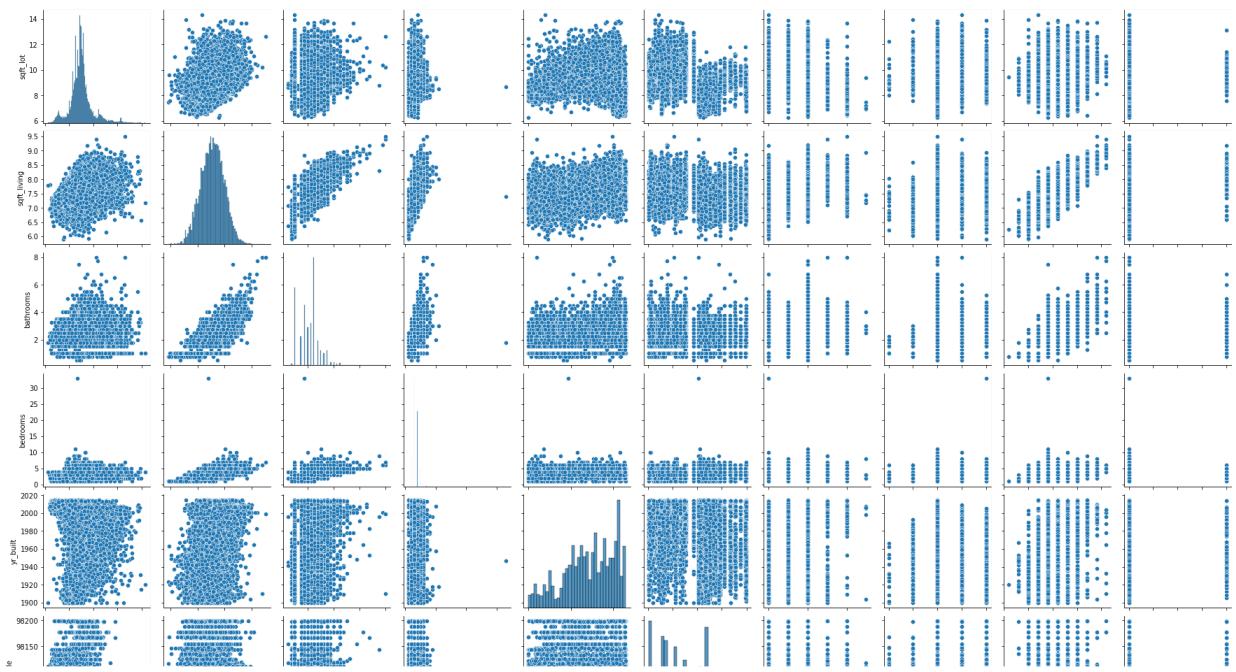

Model Feedback

In [80]:

```

1 #Looking at the final dataset in the pairplot
2 sns.pairplot(X_train_final)
3 plt.savefig("images/Pair_10.png", dpi=99)

```

Model Prediction

The best fit model will be used to make predictions for homes that have home improvements. In this case the "condition" and "grade" features for a specific group of homes in certain zipcodes. The top five zipcodes that have the most homes with a **"condition" of 3-Good or less & a "grade" of 6-Low Average or less"**. The chosen homes will all be modified to have a condition of "4-Good" and a grade of "8-Good".

These predictions will serve as samples for the real estate agents to understand the benefit of real estate data analysis. Because home value can depend on the surrounding community, grouping the homes for predictions by zipcodes helps the agent target a specific community for an extra benefit.

Dataframe Evaluation and Manipulation

```
In [81]: 1 #Copy the original dataset (with waterfront, condition and grade proces
          2 imp_df = kc_df.copy()
          3 imp_df.head()
          4
```

Out[81]:

Out of the homes in the 98188 zipcode, there was an average of 323,000 price increase, a minimum calculated value -35,000 loss and a max of 624,000 increase. The negative numbers are most likely prediction errors.

Regression Results

Model Results

The goal was to create a multilinear regression model that would be able to predict housing prices upon improvements. The model created to do this used an initial subset of data (from King County database) to process, train and test for this problem.

The final model was the fourth iteration. The intial model started as a base model linear regression model and increased in complexity with transformations (Log and One Hot Encoding) and filtering of features.

The final accuracy metrics are good enough to use the model for basic home value predictions.

Coefficient Results:

Grade Feature: For every one-unit increase in the Grade, the home value increases by about 26%.

Condition Feature: For every one-unit increase in the Condition, the home value increases by about 3%.

Sqft_living Feature: For every 5% increase in the sqft, the home value by about 20 %.

RMSE Score Results:

The refinement of our model decreased the train and test RMSE scores by over 260K to ~.197K.

Applying the Log Transformer on our train and test target parameter "price" was the primary catalyst for this decrease. The price value was initial skewed and needed to be normalized.

The final model has a ~129k RMSE. This means the predicted home price can be off by about \$197,000K.

R2 Score Results:

The final model increased its R2 score by ~.15. The best base model score was .5 and the final test's model score ended with ~.66. As we refined the model, it increased its ability to account and explain for the variation. This was due primarily to the use of multiple features and the filtering of

insignificant ones.

Linear Regression Model Assumptions:

The final model passed the linearity, normalization and homoscedasticity assumptions and failed the multicollinearity assumption.

For this particular problem we are using the model for predictions and inferential uses. Therefore, the failure of multicollinearity was not a major roadblock this time. For inferential use, a deeper evaluation on the most optimistic combinations of features to use for the model must be done.

Validation:

Our model development had a training, validation and test set. The test set that was initially split from the test set was segregated the entire model development. Using Kfold cross validation was a more robust validation method over the basic train/test split.

Model RMSE and R2 Scores:

Final Unlogged Train Mean Squared Error: 206364.0

Final Unlogged Test Mean Squared Error: 196739.0

Final Train Model Score: 0.6438531698069864

Final Test Model Score: 0.6565129767577557

Third Train RMSE (Logged): 0.3147718460539656

Third Test RMSE(Logged): 0.3075890371545622

Third Train Model Mean Score: 0.644673314060476

Third Validation Model Mean Score: 0.6414594822403191

Second Model Kfold Train Mean score: 0.6446907194384797

Second Model Validation Mean score: 0.6414405396108452

Baseline Models:

Train RMSE: 260172.0361161922

Test RMSE: 268864.35998011974

Kfold Train Mean Score: 0.4884772214299433

Kfold Validation Mean Score: 0.5000072841051805

Train/Test Split Train Model Score: 0.49091149233831743

Train/Test Split Validation Model Score: 0.494749423259338

Prediction Results

Using the trained multi-linear regression model, home prices were able to be predicted for a subset of homes. Because this problem was to predict home values after improvements, homes were chosen that had a major space for improvement.

The initial dataset used was filtered by the top five zipcodes that have the most homes with a "**condition" of 3-Average or less & a "grade" of 6-Low Average or less**".

The chosen homes were then modified to have a condition of **4-Good** and a grade of **8-Good** while all the other features stayed the same. The modified condition and grades were chosen as an objective goal. The thought was to give home owner incentives to improve upon their property, even if they do not reach the desired criteria.

These predictions will serve as samples for the real estate agents to understand the benefit of real estate data analysis. Because home value can depend on the surrounding community, grouping the homes for predictions by zipcodes helps the agent target a specific community for an extra benefit.

Home Improvement Prediction Results

Across the five chosen zipcodes, they all resulted in several hundred thousand dollar increase and minimum 100% increase in value.

Average home value differences :

- Zipcode 98118: \$ 323,500, 100% Increase
- Zipcode 98106: \$ 304,100, 100% Increase
- Zipcode 98126: \$ 266,500, 100% Increase
- Zipcode 98146: \$ 324,300, 200% Increase
- Zipcode 98168: \$ 340,300, 200% Increase

Specific zipcode example (98188) had the highest amount of homes (106) that met our criteria for needing improvement.

Zipcode 98188 home value differences:

- Average of \$ 323,500 price increase
- Lowest change of \$ 14,500 increase (35,000 loss was recorded, but most likely an outlier error).
- Highest change \$624,000 increase.

Conclusion

Limitations

Stakeholders Audience

There were several major limitations. A lot of it stemmed from understanding the domain and making processing and analysis decisions from that knowledge.

- **Limited dataset:**
 - The full dataset was filtered and scoped due to limited resources. There were attributes (features) in the dataset that would have supported a more accurate model.
 - Dataset does not take into account aesthetics. There are no features or pictures evaluating this aspect.
- **Unknown realistic "Condition" and "Grade" values:**
 - Lack of knowledge on knowing what a realistic increase in "condition" and "grade" would be from the baseline. All chosen instances in the dataset were increased to the same values. It may be unrealistic to have a home in poor condition and below minimum building standards actually increase to "good" in both.
- **Unknown affects on other variables:**
 - The "condition" and "grade" features were the only ones modified from the initial dataset. Home improvements would definitely affect those features. However, home improvements done on a home might also affect features like sqft_living, floors, bathrooms or bedrooms in some way.
- **Communal effects:**
 - The predictions were based on the modification of specific features for an individual home. The predictions did not take into account how the home improvements would affect the surrounding comparable homes. This is a common task done in real estate.
- **Model approach fit for specific problem:**
 - The model developed was for a specific problem. Understanding how home improvement affects home values and the amount of the difference. Other use cases and problems were not taken into account. There may be insights to gain from the model and predictions that
- **Time/Resources:**
 - Because of limited time and skillset a "good enough" model was delivered. The datasets, techniques, and model robustness had to be scoped.
- **Actual market culture:**
 - The dataset used wasn't the most current. These last two years have had major shifts in the supply and demand of homes. Therefore a shift in the home value estimates shift as well.
- **External effects:**
 - The model and predictions did not account for external effects that were not attributes of the home and its property.
- **Data scientist skillset:**
 - As a new data scientist the model robustness is limited due to experience and skills.

Data Science Audience

- **Dataset limitations:**
 - A subset of the dataset was used. Using the whole dataset would have given more choices to choose from in terms of correlation
 - The feature "waterfront" only had values of "Unknown", "No" and "Yes". It does not say what the waterfront view is, if the feature had a value of "Yes"
- **Linear Regression Assumptions:**
 - The multicollinearity assumption was the only assumption that clearly failed. Because of the resource and dataset scope limitations this aspect was not changed to fix this issue. If we wanted inferential analysis this would have to be fixed.
- **Limited in robustness:**

- Not having the domain knowledge, a model that allowed for more flexibility in feature combinations and value valuations would have been beneficial.
- **Iterations:**
 - There were only 4 iterations done to create a prediction model. There were a lot of changes and approaches that would have required quite a lot more iterations to refine the model from the previous feedback received.
- **Feature combinations:**
 - The feature combinations were chosen from filtering the initial set down. Using the statsmodel p-value and the VIF. There wasn't a robust method that optimizes the best combinations for the model.
- **Model error and scores:**
 - It is not fully understood if the errors of a RMSE .3 R2 .66 are acceptable for the specific problem and solution approach. Also with these errors and score, it is still not understood what the cause of the of there errors is.

Recommendations:

- **Low Hanging Fruit: Focus on major areas with high needs to bring up home values.**
 - **At a minimum promote increasing conditions (e.g. maintenance) in the homes.**
 - For every one-unit increase in the Condition, the home value increases by about 3%
 - **Promote bring homes up to code (this increases the grade, which impacts home values the most).**
 - For every one-unit increase in the Grade, the home value increases by about 26%.
 - **While improving the home recommend adding a room (e.g. bathroom, small bedroom).**
 - For every 5% increase in the sqft, the home value by about 20 %.
 - For every 1% increase in the sqft, the home value by about 4 %.

Next Steps:

- Choose and present incentives and vision of home improvement within a community. This incentivizes people and helps with accountability.
 - Choose a few zipcodes to try out and then offer feedback that would improve model accuracy or approach.
 - The communal effect will possibly increase prices even though the highest improvements may not have happened.
 - Present businesses(e.i. construction, remodeling) of the potential work to be done. Partnering with them and possibly offering discounts to the select communities would be a good incentive for communities to improve together
- Market to potential homebuyers (individuals and investors) of the potential return on investment. These homebuyers may potentially buy the homes before the improvements and then fix them up.
- Increase consultation with the data scientist/analyst to improve our domain knowledge. As both parties educate each other the model solution has a better chance at being more accurate and robust.
 - Feedback on realistic feature values after home improvement

- Having examples and case studies of home improvements specifics would help give a realistic picture to all of the stakeholder supporting the predictions and work.
